

CENG381 Stochastic Processes

Poisson Process - Answer Key 1

Q1 Solution

a) Sales rate and expected time to 10th sale:

Thinning property: if arrivals are Poisson(λ) and each is independently kept with probability p , the kept arrivals form a Poisson process with rate $\lambda' = \lambda * p$.

$$\lambda' = 5 * 0.4 = 2 \text{ sales per hour}$$

The time of the n -th sale, $S_n = X_1 + \dots + X_n$, where each $X_k \sim \text{Exponential}(\lambda')$ are i.i.d. inter-sale times.

$$\begin{aligned} E[S_{10}] &= E[X_1] + \dots + E[X_{10}] = 10 * (1/\lambda') \\ &= 10 * (1/2) = 5 \text{ hours} \end{aligned}$$

b) P(no sales in first hour):

Using the Poisson PMF with rate $\lambda' = 2$, time $t = 1$, $n = 0$:

$$\begin{aligned} P(N(1) = 0) &= (\lambda'^1)^0 * e^{-(\lambda'^1)} / 0! \\ &= 1 * e^{(-2)} / 1 \\ &= e^{(-2)} \\ &\sim 0.1353 \end{aligned}$$

There is about a 13.5% chance of making no sales in the first hour.

c) P(exactly 3 sales in first 2 hours):

Using the Poisson PMF with rate $\lambda' = 2$, time $t = 2$, $n = 3$:

$$\begin{aligned} P(N(2) = 3) &= (\lambda'^2)^3 * e^{-(\lambda'^2)} / 3! \\ &= (2^2)^3 * e^{(-4)} / 6 \\ &= 4^3 * e^{(-4)} / 6 \\ &= 64 * e^{(-4)} / 6 \\ e^{(-4)} &\sim 0.01832 \\ P(N(2) = 3) &\sim 64 * 0.01832 / 6 \sim 1.1725 / 6 \sim 0.1954 \end{aligned}$$

There is about a 19.5% chance of exactly 3 sales in the first 2 hours.

Poisson Process - Answer Key 1

Q2 Solution

a) Distribution of S_1 (time of first call):

$S_1 > t$ means no calls arrive in $[0, t]$, i.e. $N(t) = 0$.

$$\begin{aligned}P(S_1 > t) &= P(N(t) = 0) \\&= (\lambda t)^0 * e^{-(\lambda t)} / 0! \\&= e^{-(\lambda t)}\end{aligned}$$

This is exactly the survival function of an Exponential(λ) distribution: $P(\text{Exp}(\lambda) > t) = e^{-(\lambda t)}$.

Therefore $S_1 \sim \text{Exponential}(\lambda = 4 \text{ calls/hour})$. (OK)

b) P(first call within 15 minutes = 0.25 hours):

$$\begin{aligned}P(S_1 \leq 0.25) &= 1 - P(S_1 > 0.25) \\&= 1 - e^{-(\lambda * 0.25)} \\&= 1 - e^{-(4 * 0.25)} \\&= 1 - e^{-1} \\&\sim 1 - 0.3679 = 0.6321\end{aligned}$$

There is about a 63.2% chance of the first call arriving within 15 minutes.

c) Waiting time from S_1 to S_2 :

Key property used: INDEPENDENT INCREMENTS.

The number of calls in any interval depends only on the LENGTH of the interval, not on when it starts or what happened before.

In particular, the time from S_1 to S_2 (the 2nd inter-arrival time X_2) is independent of S_1 and has the SAME distribution:

$$X_2 = S_2 - S_1 \sim \text{Exponential}(\lambda = 4)$$

This is the MEMORYLESS property of the exponential distribution.

$$\begin{aligned}E[S_2] &= E[S_1] + E[X_2] = 1/\lambda + 1/\lambda = 2/\lambda \\&= 2/4 = 0.5 \text{ hours} = 30 \text{ minutes}\end{aligned}$$

CENG381 Stochastic Processes

Poisson Process - Answer Key 1

Q3 Solution

a) Binomial model $X_m \sim \text{Binomial}(m, \lambda T/m)$:

In each of the m sub-intervals, there is either 0 or 1 arrival, each with probability $p_m = \lambda T/m$. The total count X_m is the sum of m independent Bernoulli(p_m) trials:

$$X_m \sim \text{Binomial}(m, \lambda T/m)$$

$$E[X_m] = m * p_m = m * (\lambda T/m) = \lambda T$$

$$\begin{aligned}\text{Var}[X_m] &= m * p_m * (1 - p_m) \\ &= \lambda T * (1 - \lambda T/m) \\ &\rightarrow \lambda T \text{ as } m \rightarrow \infty\end{aligned}$$

b) Convergence to Poisson(λT) as $m \rightarrow \infty$:

Binomial PMF for a fixed n :

$$P(X_m = n) = C(m, n) * (\lambda T/m)^n * (1 - \lambda T/m)^{m-n}$$

Expand each factor as $m \rightarrow \infty$:

$$\begin{aligned}C(m, n) &= m(m-1)\dots(m-n+1) / n! \\ &\sim m^n / n! \quad (\text{for fixed } n, \text{ large } m)\end{aligned}$$

$$(\lambda T/m)^n = (\lambda T)^n / m^n$$

$$\begin{aligned}(1 - \lambda T/m)^{m-n} &\sim (1 - \lambda T/m)^m \\ &\rightarrow e^{-(\lambda T)} \text{ as } m \rightarrow \infty \\ &[\text{using the standard limit: } (1 - x/m)^m \rightarrow e^{-x}]\end{aligned}$$

Combining:

$$\begin{aligned}P(X_m = n) &\rightarrow (m^n / n!) * ((\lambda T)^n / m^n) * e^{-(\lambda T)} \\ &= (\lambda T)^n * e^{-(\lambda T)} / n!\end{aligned}$$

This is exactly the Poisson(λT) PMF. (OK)

CENG381 Stochastic Processes

Poisson Process - Answer Key 1

c) Forward equations and verification:

Derivation of $dp_j(t)/dt$:

In the small interval $[t, t+\Delta t]$:

$$\begin{aligned} P(N(t+\Delta t)=j) &= P(N(t)=j) * P(0 \text{ arrivals in } \Delta t) \\ &+ P(N(t)=j-1) * P(1 \text{ arrival in } \Delta t) \\ &+ P(N(t) \leq j-2) * P(2+ \text{ arrivals in } \Delta t) \end{aligned}$$

Using $P(0 \text{ arrivals in } \Delta t) = 1 - \lambda \Delta t + o(\Delta t)$

and $P(1 \text{ arrival in } \Delta t) = \lambda \Delta t + o(\Delta t)$:

$$p_j(t+\Delta t) = p_j(t)(1-\lambda \Delta t) + p_{j-1}(t)(\lambda \Delta t) + o(\Delta t)$$

Rearrange and divide by Δt , then take $\Delta t \rightarrow 0$:

$$dp_j(t)/dt = -\lambda p_j(t) + \lambda p_{j-1}(t) \quad \text{for } j \geq 1$$

Verification that $p_j(t) = (\lambda t)^j * e^{-(\lambda t)} / j!$ satisfies this:

Left side: dp_j/dt

$$\begin{aligned} &= d/dt [(\lambda t)^j * e^{-(\lambda t)} / j!] \\ &= [j * \lambda * (\lambda t)^{j-1} * e^{-(\lambda t)} - \lambda * (\lambda t)^j * e^{-(\lambda t)}] / j! \\ &= \lambda * e^{-(\lambda t)} / j! * [j * (\lambda t)^{j-1} - (\lambda t)^j] \end{aligned}$$

Right side: $-\lambda p_j + \lambda p_{j-1}$

$$\begin{aligned} &= -\lambda * (\lambda t)^j * e^{-(\lambda t)} / j! \\ &+ \lambda * (\lambda t)^{j-1} * e^{-(\lambda t)} / (j-1)! \\ &= \lambda * e^{-(\lambda t)} * [-(\lambda t)^j / j! + (\lambda t)^{j-1} / (j-1)!] \\ &= \lambda * e^{-(\lambda t)} / j! * [-(\lambda t)^j + j * (\lambda t)^{j-1}] \end{aligned}$$

Left side = Right side (OK)

The Poisson PMF satisfies the forward equations.
